

# Maximize Oxidation Ditch Bio-P Performance

By

Jack Wendler/Ripon WWTF

# Ripon WWTF

Design 1.8 MGD

Discharge Limits

Parameter	Week Average Limit	Monthly Average Limit
BOD, mg/l (Varying based on time of year)	8.2-16	8.2-16
TSS, mg/l	10	10
Ammonia, mg/L (Varying based on time of year)	2.2-5.1	2.2-5.1
Total Phosphorus, mg/L	--	1.0

# Ripon WWTF

- 1 Manager and 3 Operators
- Onsite Laboratory
  - BOD/TSS/TP/NH<sub>3</sub>-N/pH
  - Various process control testing to optimizing system
- 2003-2004 Upgrade
  - Fine Screen
  - 2 parallel oxidation ditches
  - 2 new final clarifiers
  - Biological Phosphorus Removal anaerobic zones ahead of ditches
  - UV Disinfection
  - Upgrade tertiary filtration – installed different media

**Bio-P Anaerobic Zones**

**Headworks**

**Oxidation Ditches**

# Covered Final Clarifiers

# UV/Plant Discharge

**GBT**

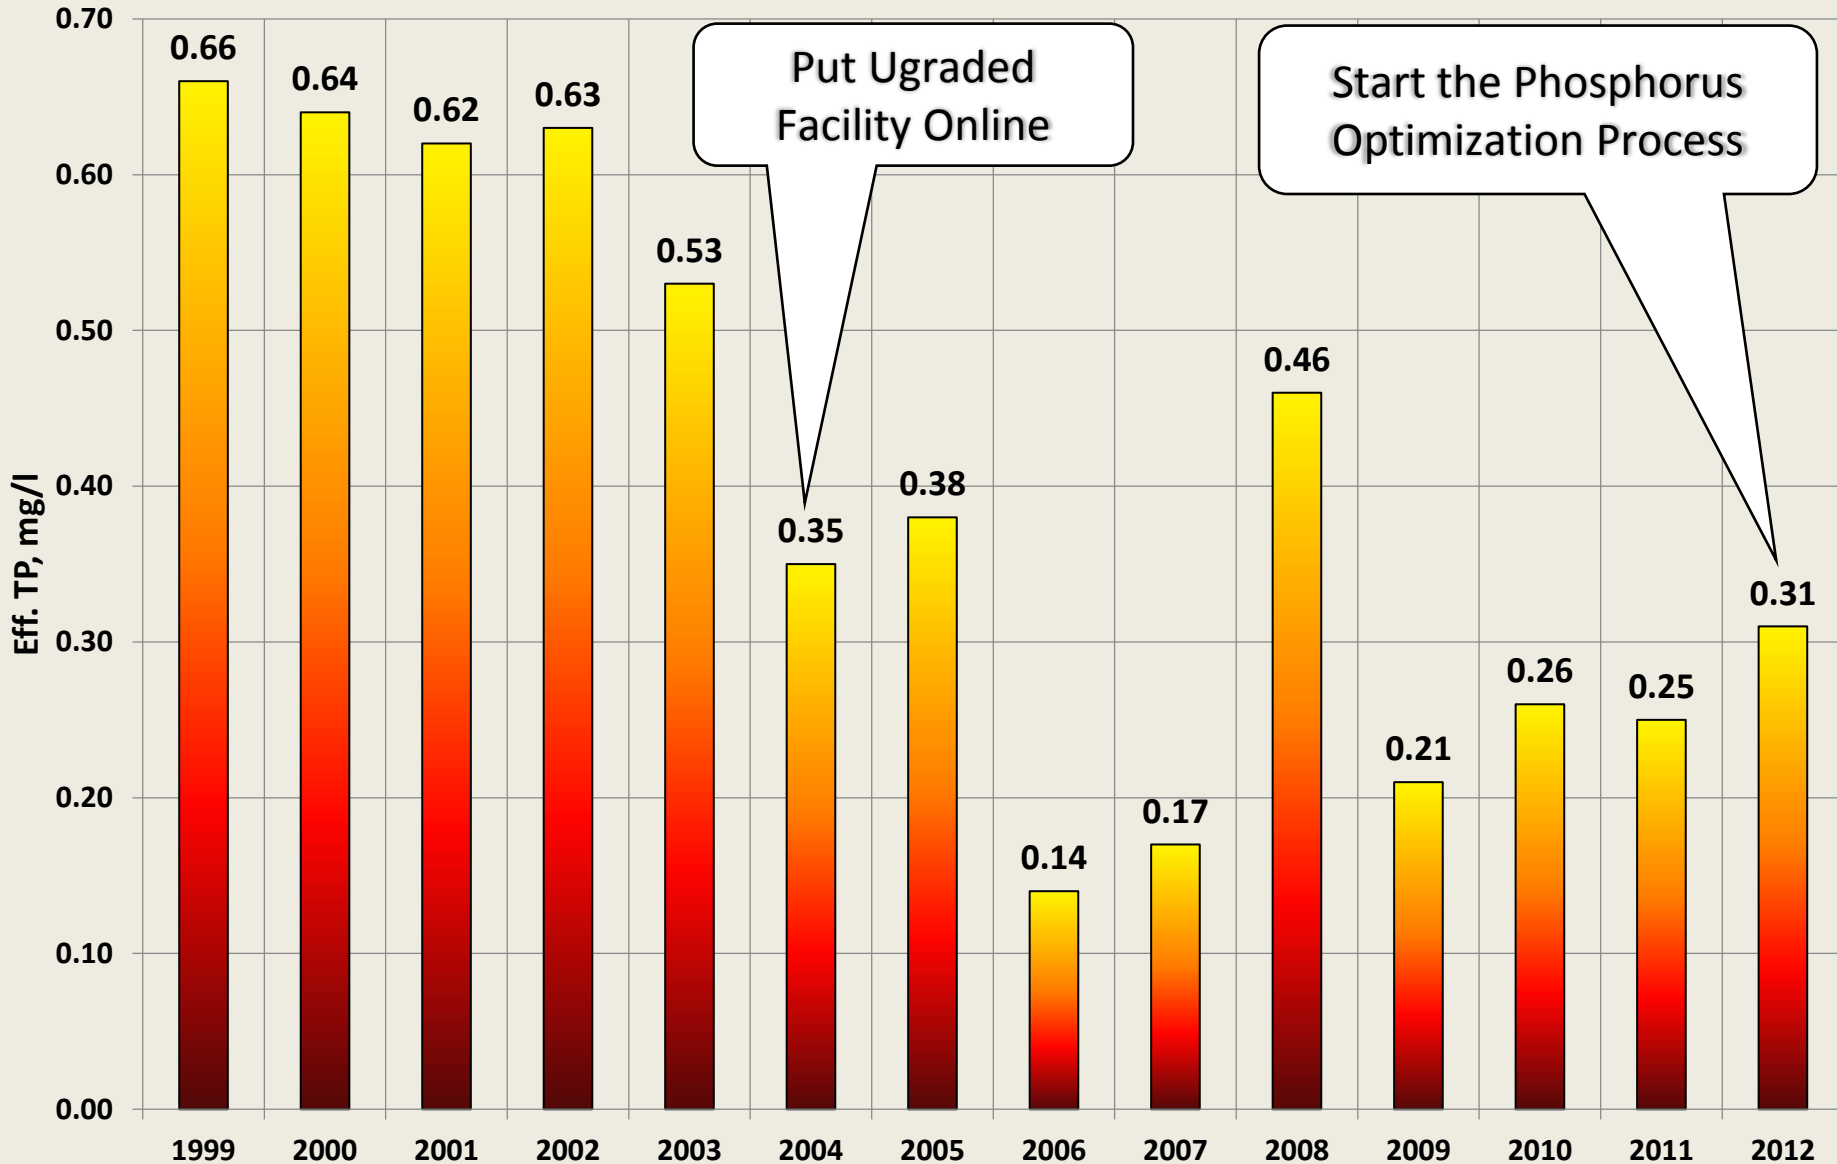

# Major Contributors

# Starting Optimization

- Staff started phosphorus optimization moves in 2012 in anticipation of its upcoming DNR discharge permit
- New permit was issued in 2014
- Permit requires compliance with a 0.075 mg/l TP limit in 2023

# Starting Point - BEFORE Optimization

# Optimization Challenges

- Focus on Bio-P and Final Filtrate vs. Chemical Optimization
- The following questions came up as staff looked in Bio-P optimization....
  - How can we reduce the impact of side stream nitrates( $\text{NO}_3\text{-N}$ ) and ortho-phosphorus ( $\text{PO}_4\text{-P}$ ) on Bio-P system?
  - How can we improve the anaerobic and anoxic zones in the Bio-P system?

# Possible Options for Changes in Operations

- Reduce  $\text{NO}_3\text{-N}$  and  $\text{PO}_4\text{-P}$  in GBT filtrate
  - Holding tank operation
  - General GBT maintenance

# Possible Options for Changes in Operations

- Ways to improve anaerobic and anoxic zones in Bio-P system
  - RAS Control
  - ORP and D.O. control in ditches
- Review effluent tertiary filter operation for possible improvement in performance

# Why explore the side streams?

- For every lb. of  $\text{NO}_3\text{-N}$  in the side stream you will use up 4 lbs. of influent BOD denitrifying the  $\text{NO}_3\text{-N}$  in the anaerobic zone
- For every lb. of  $\text{PO}_4\text{-P}$  in the side stream you need an additional 20 lbs. more of influent BOD to biologically treat the P

# Why explore the side streams?

- Jun '12 noticed difference in GBT filtrate  $\text{PO}_4\text{-P}$  concentrations, mg/l
  - Holding tank #1 – 3.3
  - Holding tank #2 – 14.1 - blower was offline
- Jul '12
  - GBT filtrate – 28.4 and 34.6

# Why explore the side streams?

- Jul '12 in the GBT filtrate the  $\text{NO}_3\text{-N}$  concentration was an average 80 mg/l
- These high concentration of  $\text{NO}_3\text{-N}$  &  $\text{PO}_4\text{-P}$  have an adverse affect on the Bio-P

# Efforts to reduce GBT $\text{NO}_3\text{-N}$ and $\text{PO}_4\text{-P}$ concentration

- Maintain adequate D.O. in holding so P does not release in holding tank
- Decreased Hydraulic Retention Time (HRT) by reducing operating level in holding tank
  - Reduces conversion of organic nitrogen to ammonia and then  $\text{NO}_3\text{-N}$

# Efforts to reduce GBT $\text{NO}_3\text{-N}$ and $\text{PO}_4\text{-P}$ concentration

- Staff experimented with GBT maintenance to reduce  $\text{PO}_4\text{-P}$
- Changed rubber seals and scrapers more often
- Staff cleaned belt more often
- Together both have improved the quality of the GBT filtrate resulting in less  $\text{PO}_4\text{-P}$  being recycled. It also resulted in lower polymer consumption

# GBT SEALS

# Efforts to Improve Anaerobic Zone

- Experimented with slowing the RAS flow rate
- Rational - reducing RAS flow will increase RAS sludge retention time in the final clarifier blanket helping to reduce ORP. When RAS sludge arrives in anaerobic zone it has a lower ORP improving the anaerobic zone quality
- Controlled as % of Influent – initial setting 70%
- After months of adjustment setting now at 55%

# Efforts to Improve Anaerobic and Anoxic Zones

- **Aeration Control – Inline ORP Probe with set point**

- Any inline probe needs routine maintenance/cleaning
- Oxidation Ditch D.O. are measured 7 days/week

# Efforts to Improve Anaerobic and Anoxic Zones

- 2012 D.O. was 1.0 ppm at the tail end of oxidation just before the secondary aerator
- In 2012 the ORP control set point for the aerator's was 170 mV this would achieve the desired 1.0 ppm D.O.
- Over the course of time staff experimented with a lower D.O. and ORP in the ditch
- Present D.O. target is 0.7 ppm and ORP aerator set point control is 93 mV

# Effectives of Reduced ORP Set Point

—△— Oxidation Ditch #1 ORP Setpoint, mV —○— Oxidation Ditch #1 D.O. ppm  
—■— Oxidation Ditch #1 D.O. @ ORP Probe

# Efforts to Improve Anaerobic and Anoxic Zones

Rational – Reducing the D.O. (ORP) in the ditch accomplishes two things;

1. Help to create a condition (lower ORP) for the DENITRIFYING organisms to act on  $\text{NO}_3\text{-N}$
2. Bring the overall ORP lower in BPR system (oxidation ditch/final clarifier sludge blanket/anaerobic zones). This helps provide better performance in the anaerobic zone – PUSHING IT MORE ANAEROBIC

# Last But Not Least – Optimize Effluent Tertiary Filter System

- Before 2012 staff experimented with effluent tertiary filter backwashing to reduce effluent TSS and in turn reduce effluent TP.
- Through experimentation staff found back washing each filter (there are 4 filters) everyday (manual mode vs. auto) improved effluent TSS and in turn effluent TP
- Staff also found out that organisms growing in the filters can effect the activated sludge - filaments

# Results of Operational Changes

- A combination of the following items all attributed to an improved Bio-P performance
- Reducing HRT in holding tank
- Increased levels of maintenance on GBT
- Reduce RAS flow rate
- Decrease both D.O. and ORP levels in the oxidation ditches – This option seemed to have the largest impact on increasing Bio-P performance
- Increase effluent tertiary filter backwashing

# Community Appreciation

## Anglers & Effluent

City of Ripon, WI

"Cookietown USA" faced the strictest effluent limits in the State. Ripon, population 7,630, is supported by 2,300 industrial jobs. Earth Tech saved the City approximately \$1.5 million with a first-of-its-kind technologically sophisticated yet easy-to-operate automated ORP probe system. This supercharged activated sludge process averted costly installation of pretreatment facilities by local industries. Sewer rates are now 25% below the state average. Treatment is affordable for industries. Jobs have been saved. Quality effluent flows into Silver Creek, a sensitive tributary to pristine Green Lake. Phosphorus reduction of 2,000+ lbs annually is restoring health to the waterways. Trout are now splashing in Silver Creek, and the air in "Cookietown" is sweet.

*Enhanced nutrient removal and high performance final clarifiers exceed the strict effluent limits of 6 mg/L BOD, 10 mg/L suspended solids, 6 mg/L ammonia, and 1 mg/L phosphorus.*

- ORP probes automate oxidation ditch process control and optimize biological removal of BOD, nitrogen, and phosphorus
- ORP probes provide quick process stabilization under variable loads
- Automated aeration control and supplemental nitrogen feed maintains constant conditions
- High-performance clarifiers with energy dissipating inlets eliminate tertiary filtration

### Effluent Quality

# Conclusion

- Ripon's staff found that through a variety of operational changes they were able to drive the *Biology* and have noticeable impact on the Bio-P performance of their system
- Educated experimentation in an orderly fashion with your Bio-P system can have positive effects on Bio-P performance
